SANOS parametric: opposite long-claim hedge versus digital payout

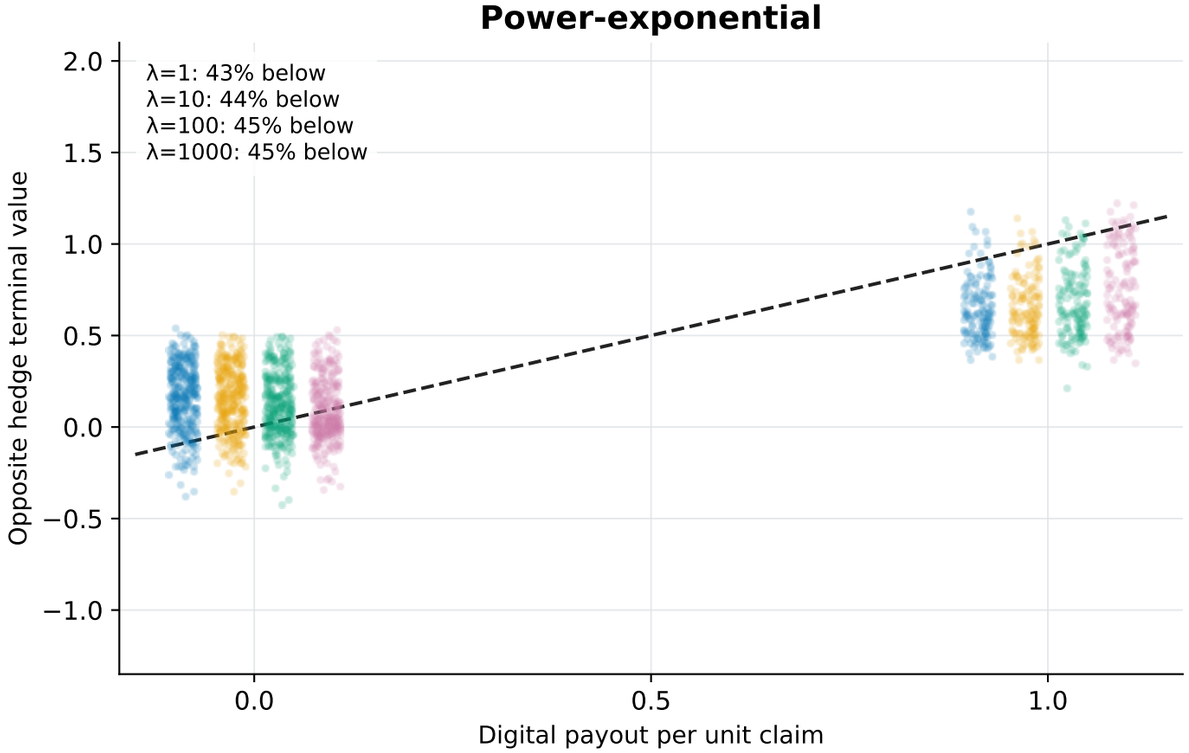

Mean-variance

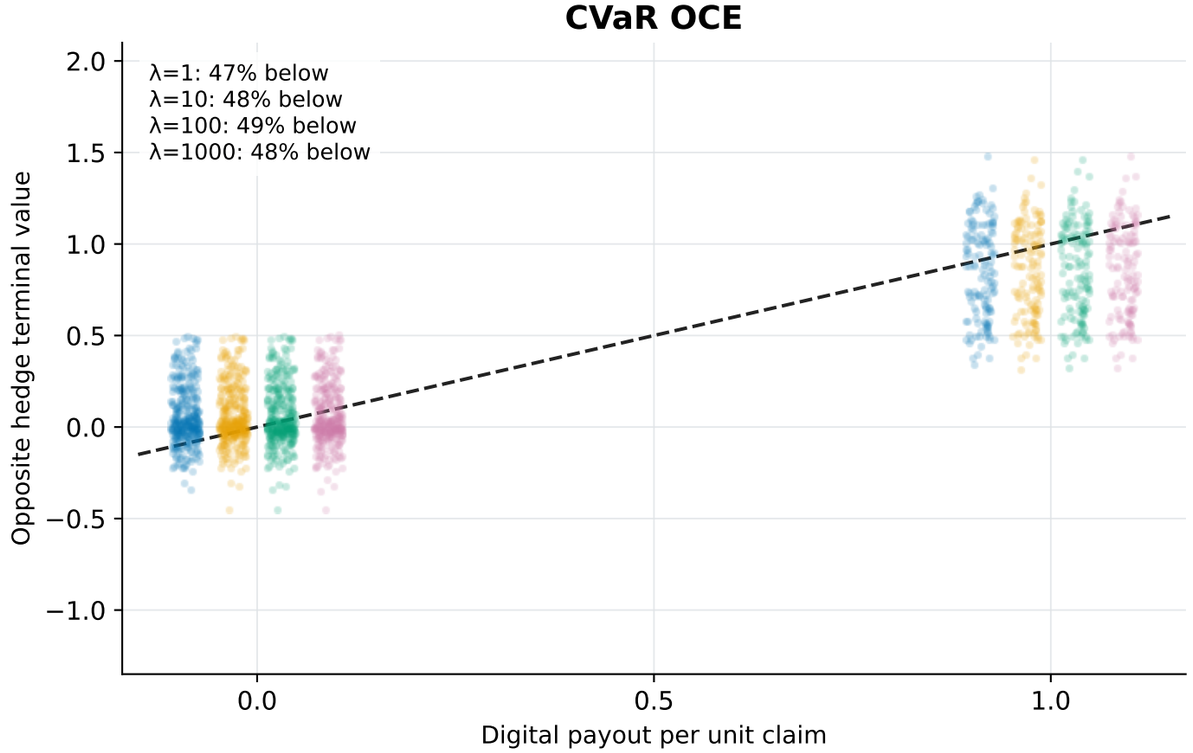

Entropy

Power-exponential

CVaR OCE

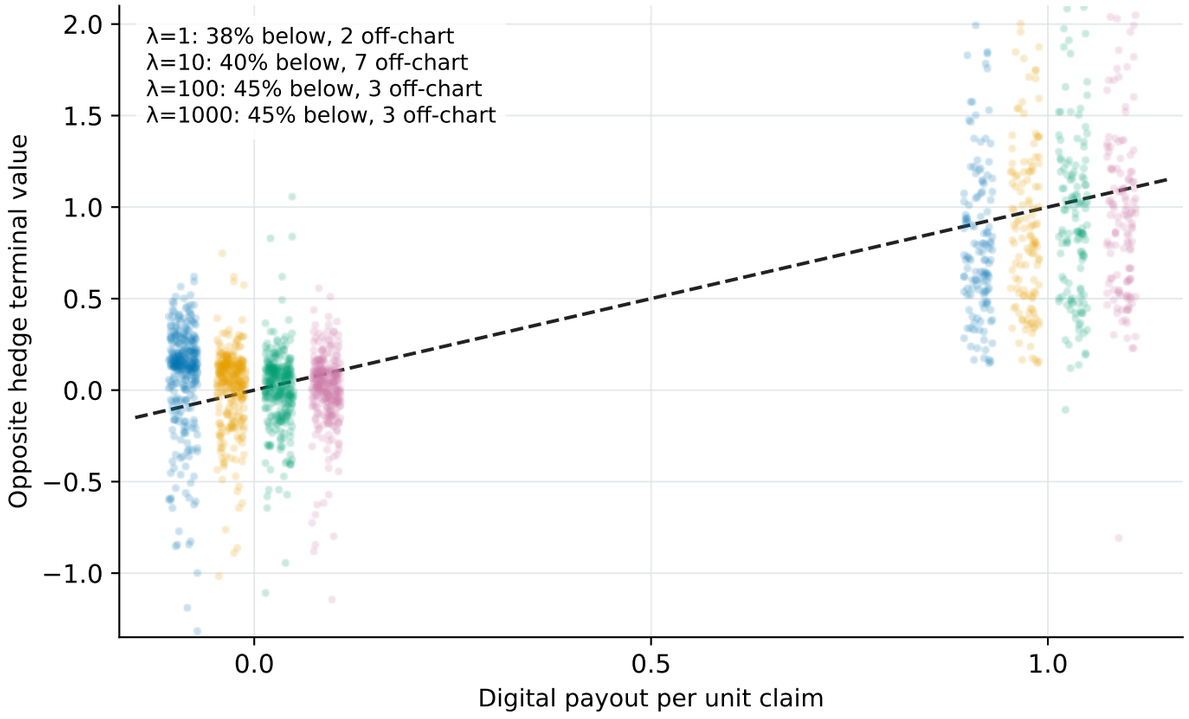

λ = 1 λ = 10 λ = 100 λ = 1000

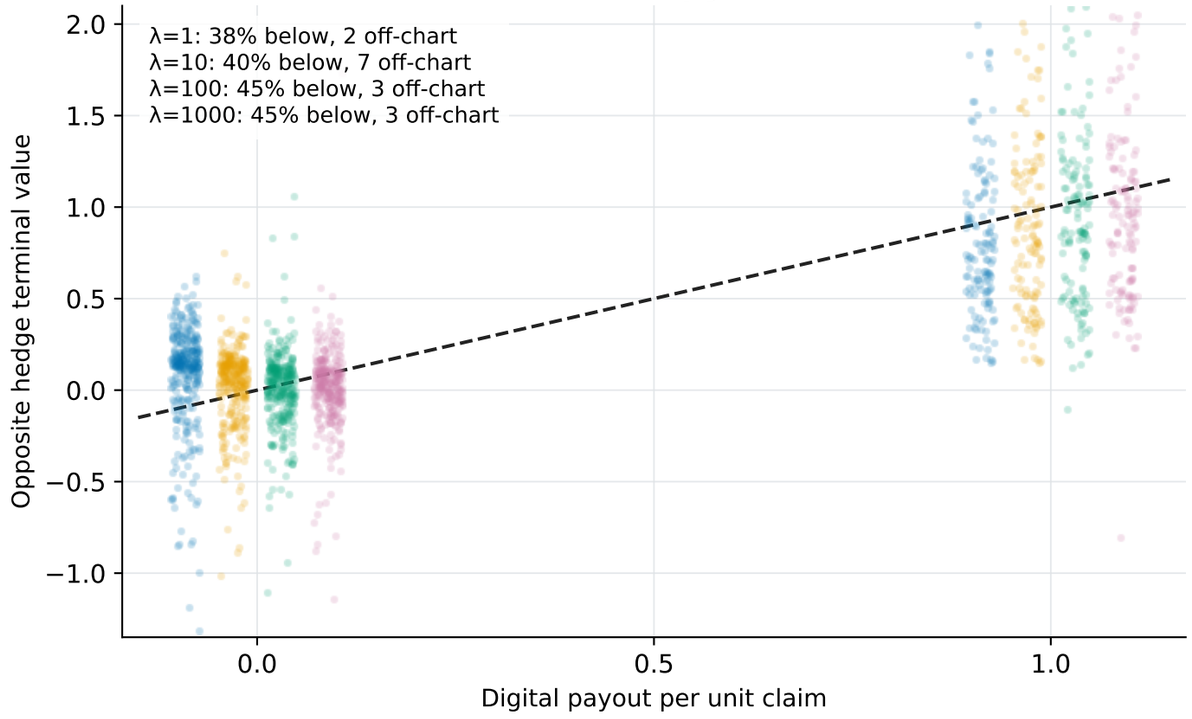

Out-of-sample market transitions; 44 dates × 10 digitals per complete cell. Below diagonal violates short-side coverage at the market premium. These are reversed long-side actions, not separately optimized superhedges.

SANOS historical PCA: opposite long-claim hedge versus digital payout

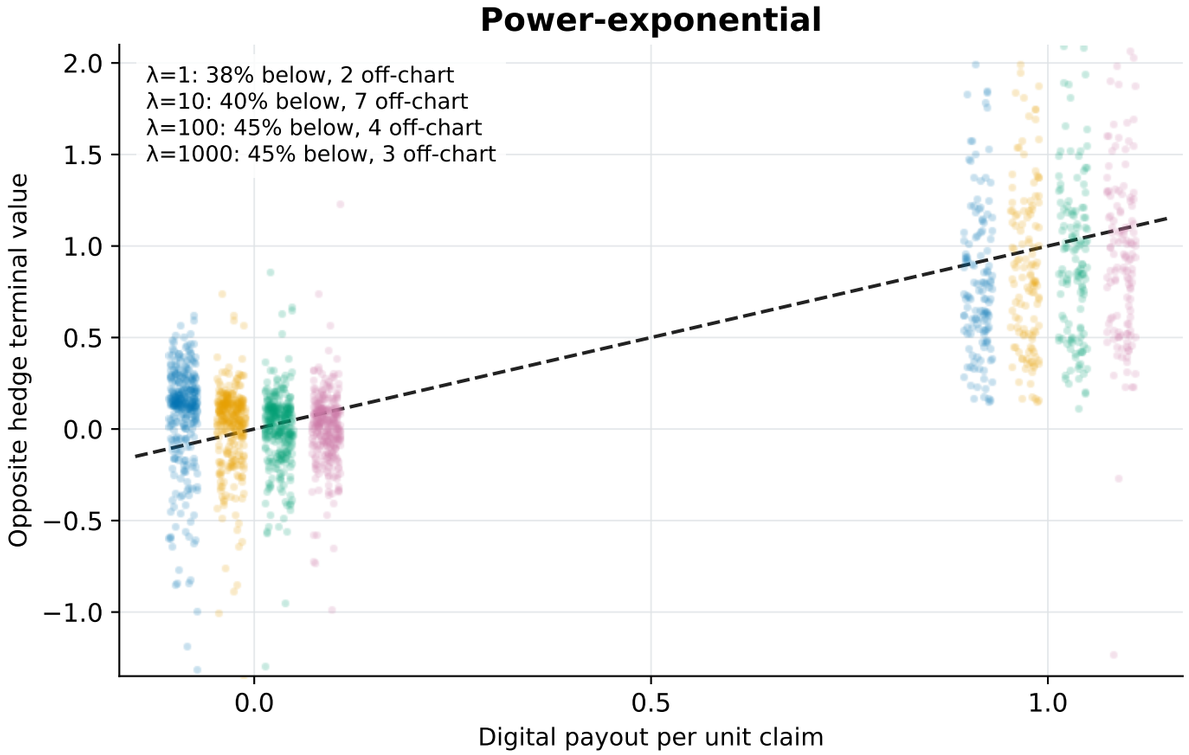

Mean-variance

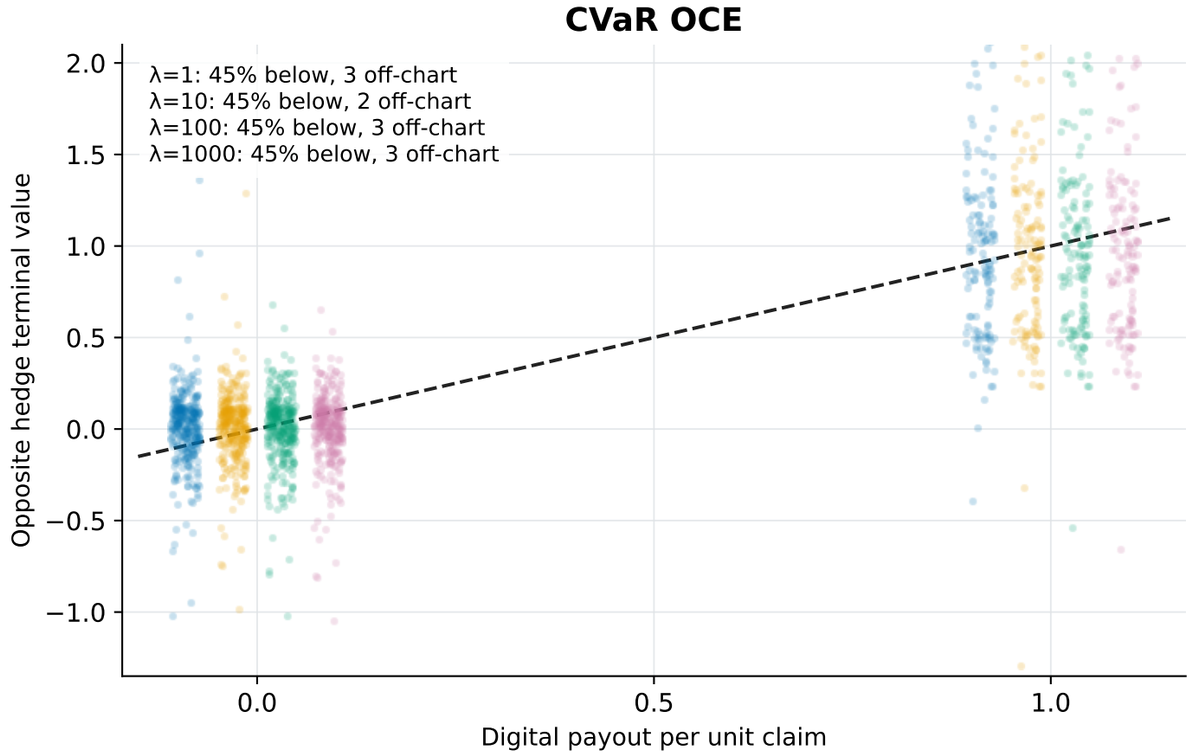

Entropy

Power-exponential

CVaR OCE

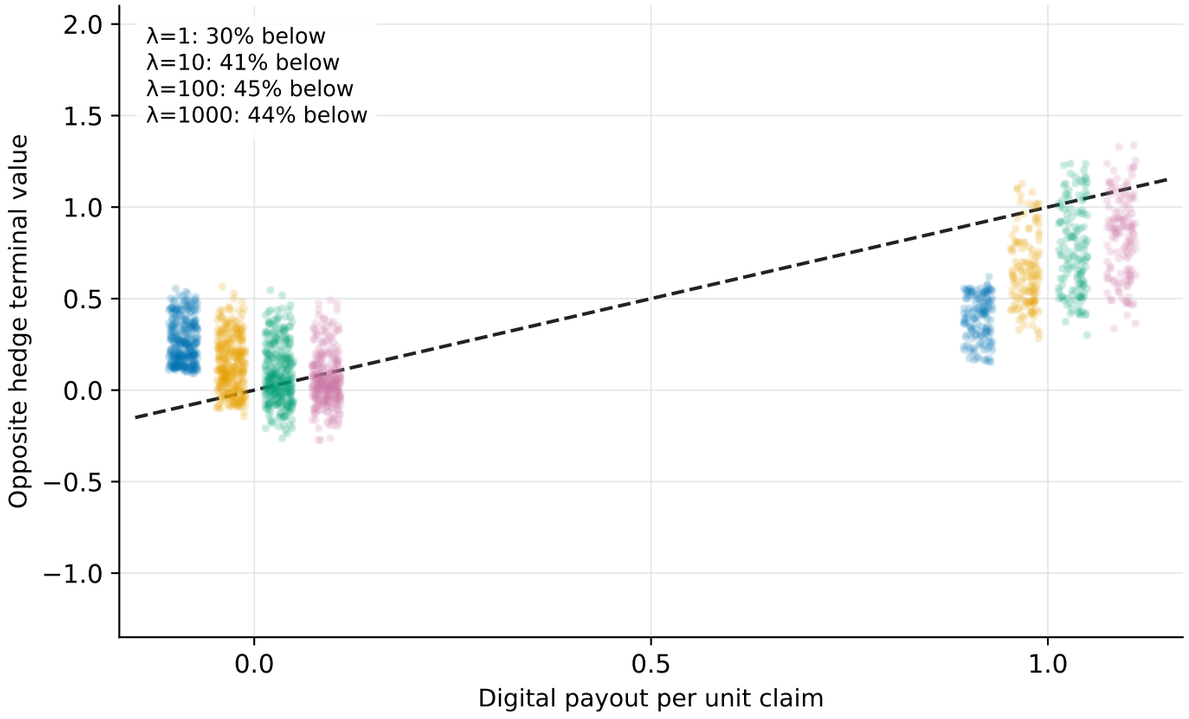

λ = 1 λ = 10 λ = 100 λ = 1000

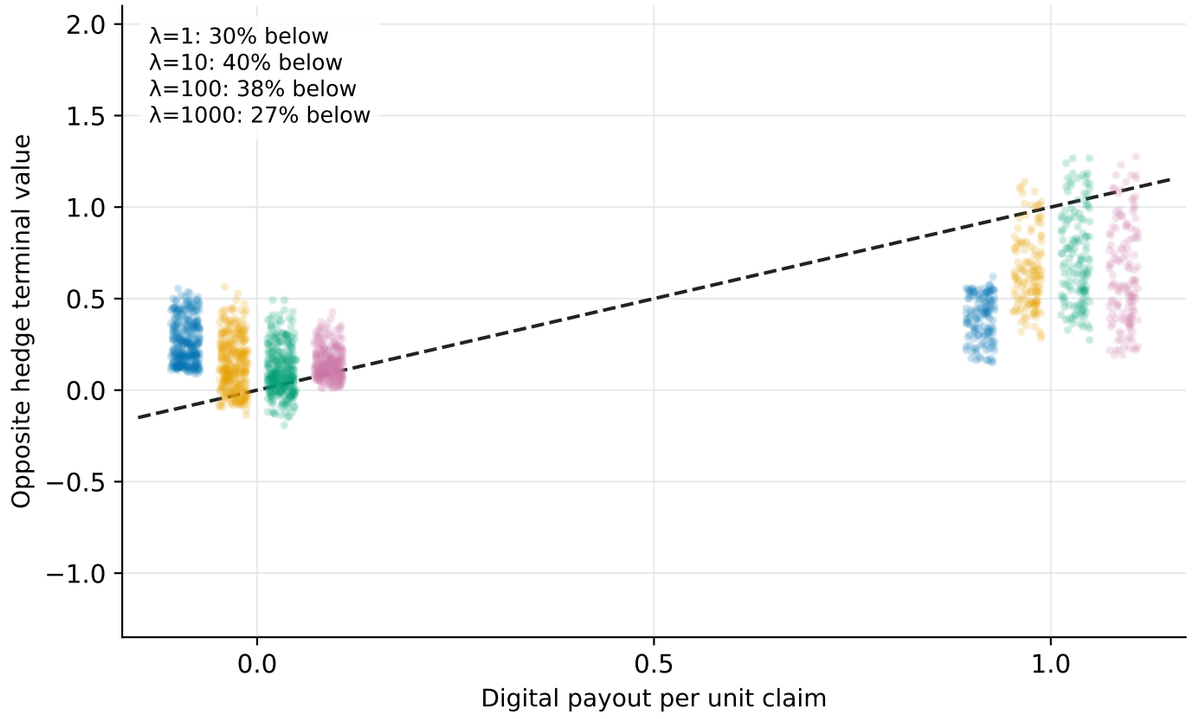

Out-of-sample market transitions; 44 dates × 10 digitals per complete cell. Below diagonal violates short-side coverage at the market premium. These are reversed long-side actions, not separately optimized superhedges.

SANOS historical: opposite long-claim hedge versus digital payout

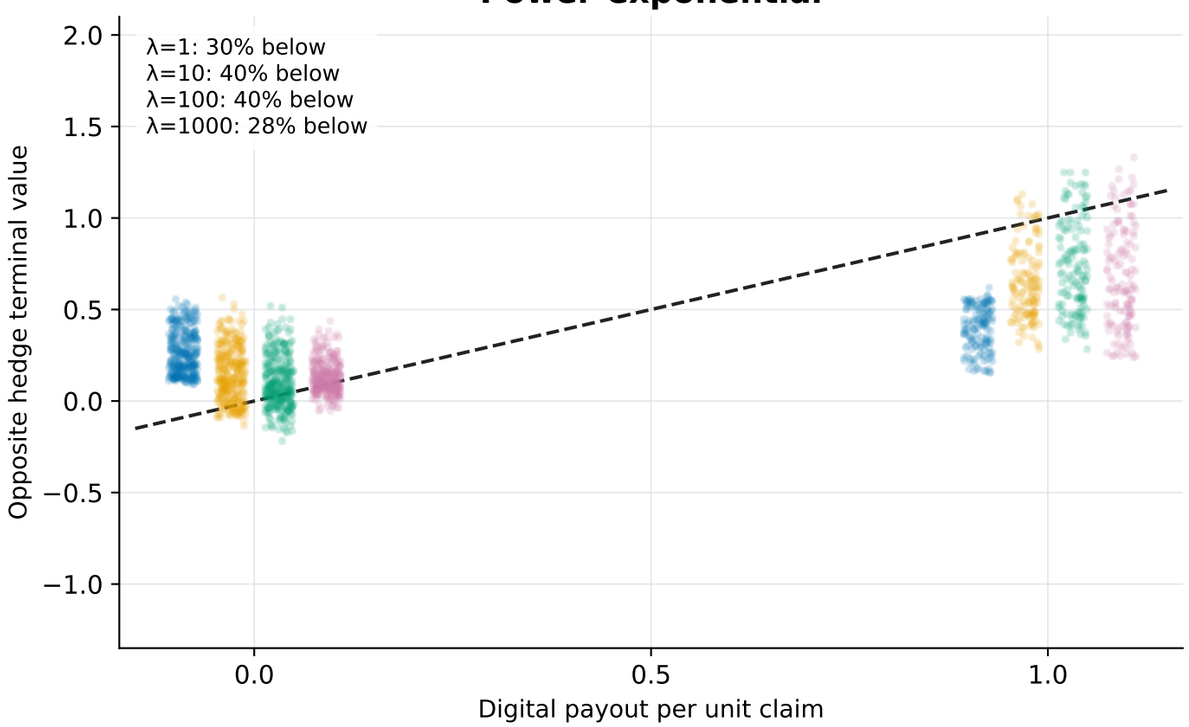

Mean-variance

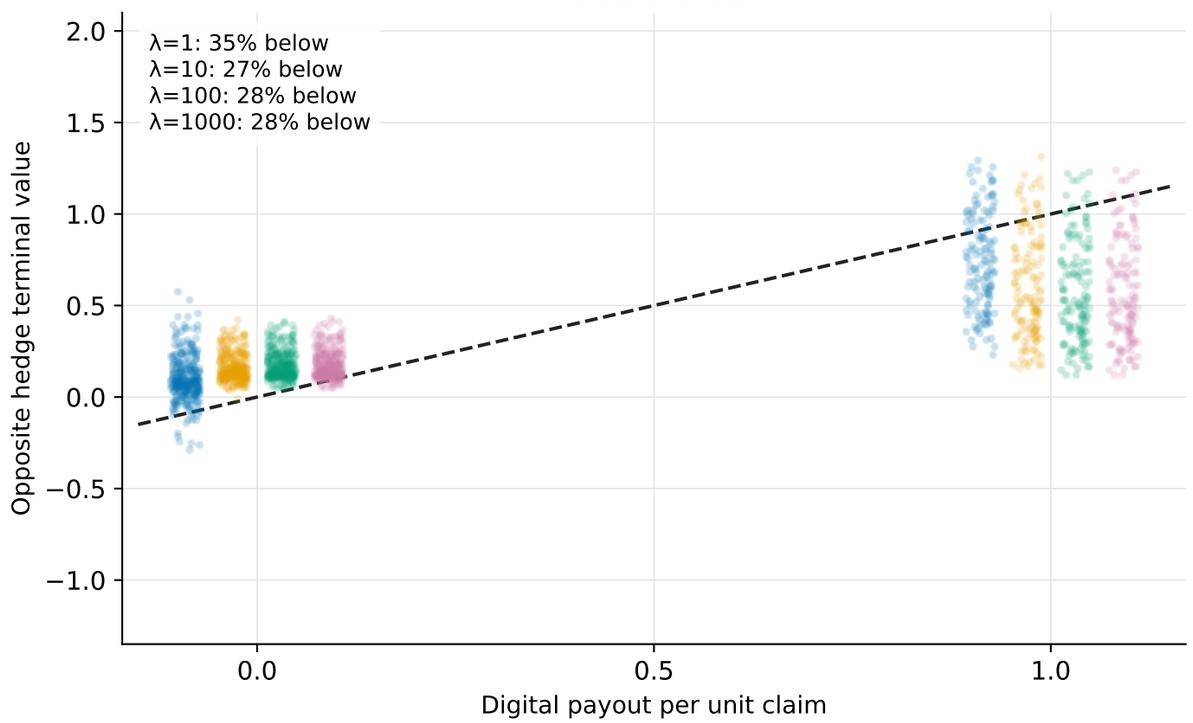

Entropy

Power-exponential

CVaR OCE

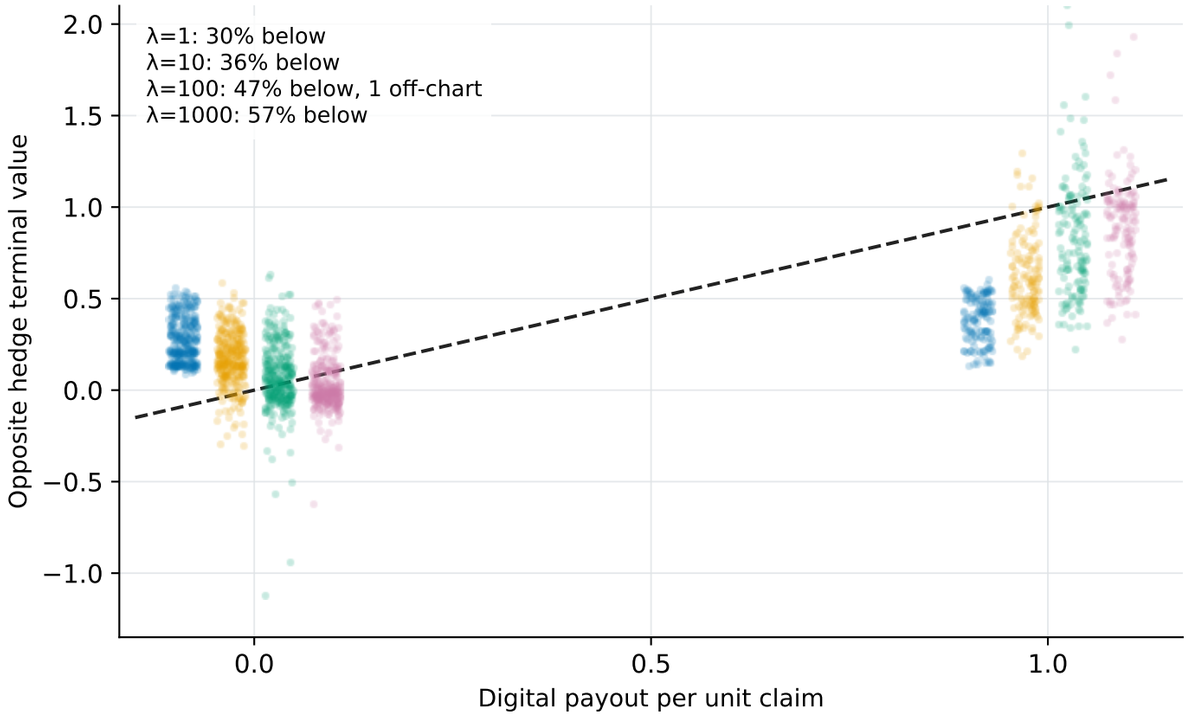

λ = 1 λ = 10 λ = 100 λ = 1000

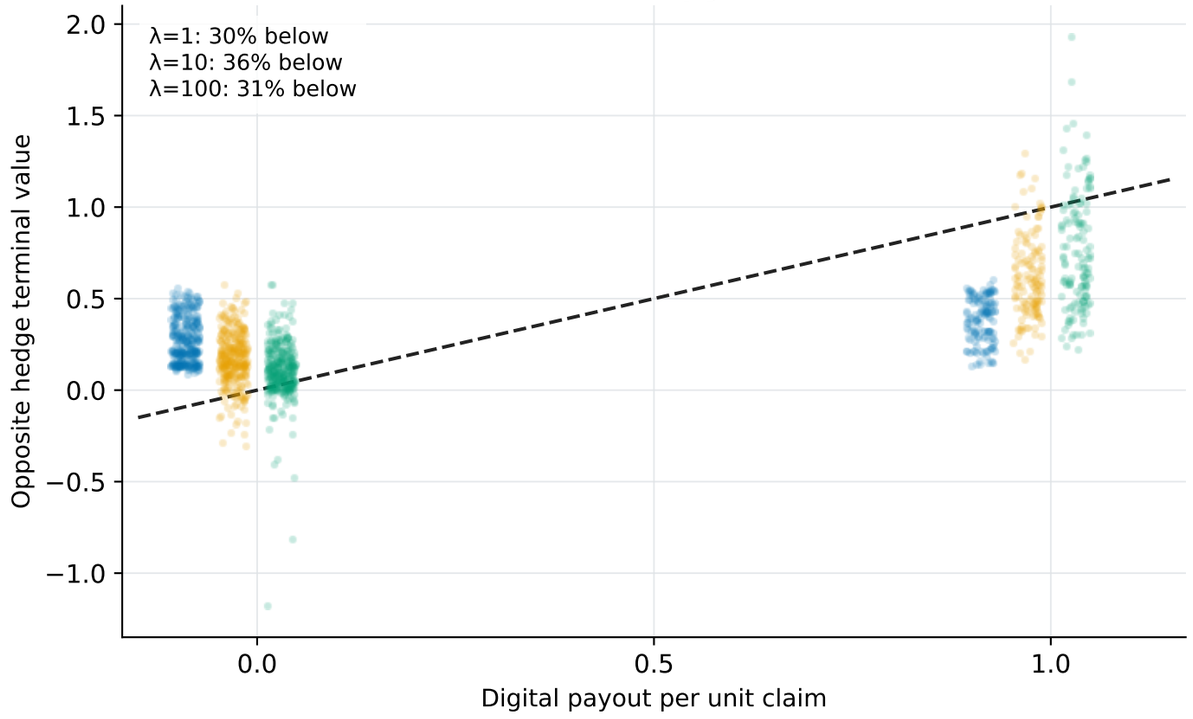

Out-of-sample market transitions; 44 dates × 10 digitals per complete cell. Below diagonal violates short-side coverage at the market premium. These are reversed long-side actions, not separately optimized superhedges.

FuNVol: opposite long-claim hedge versus digital payout

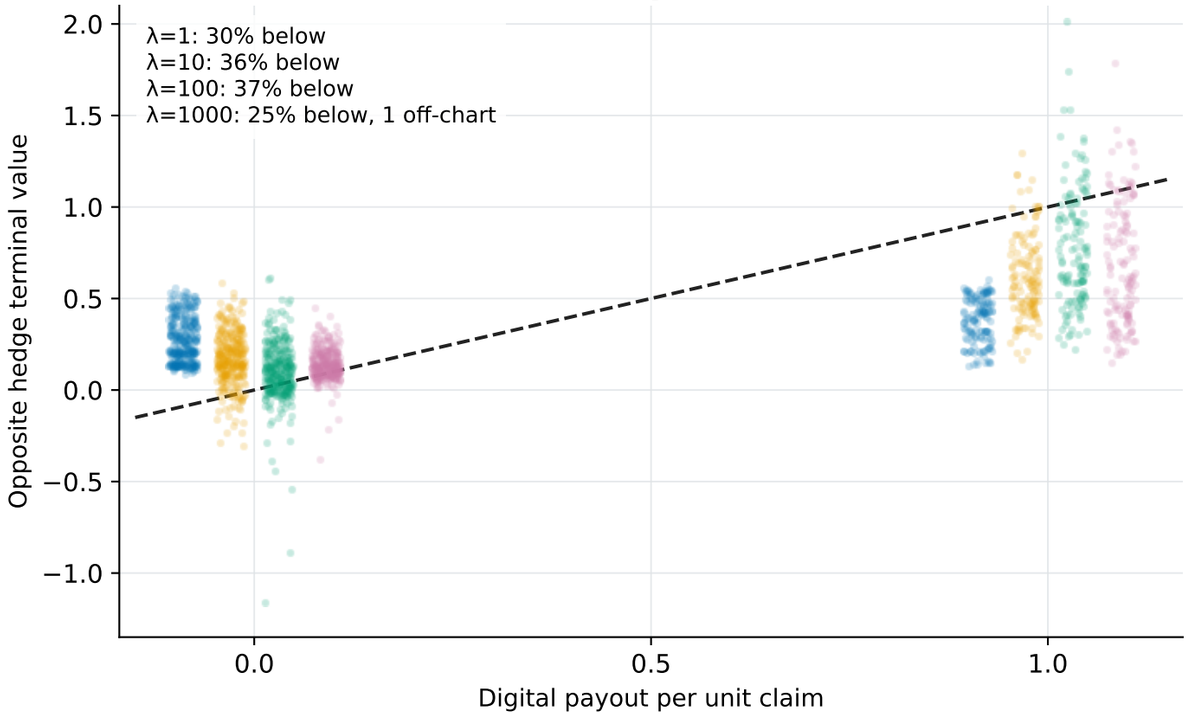

Mean-variance

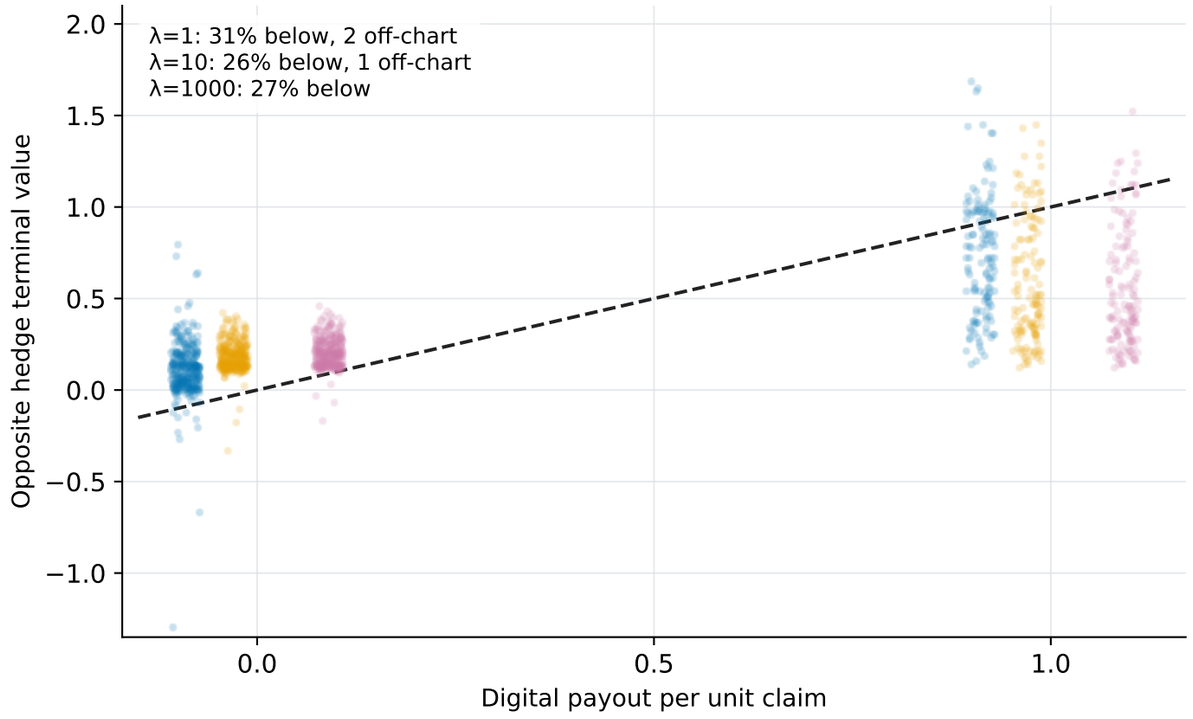

Entropy

Power-exponential

CVaR OCE

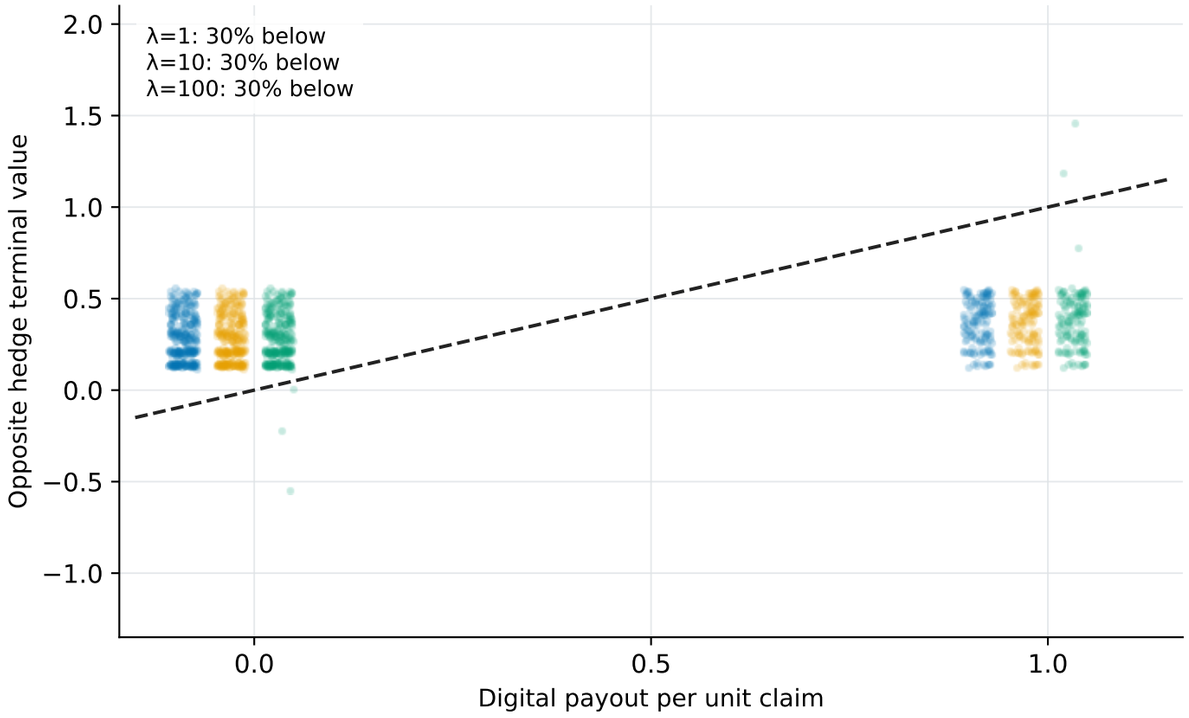

λ = 1 λ = 10 λ = 100 λ = 1000

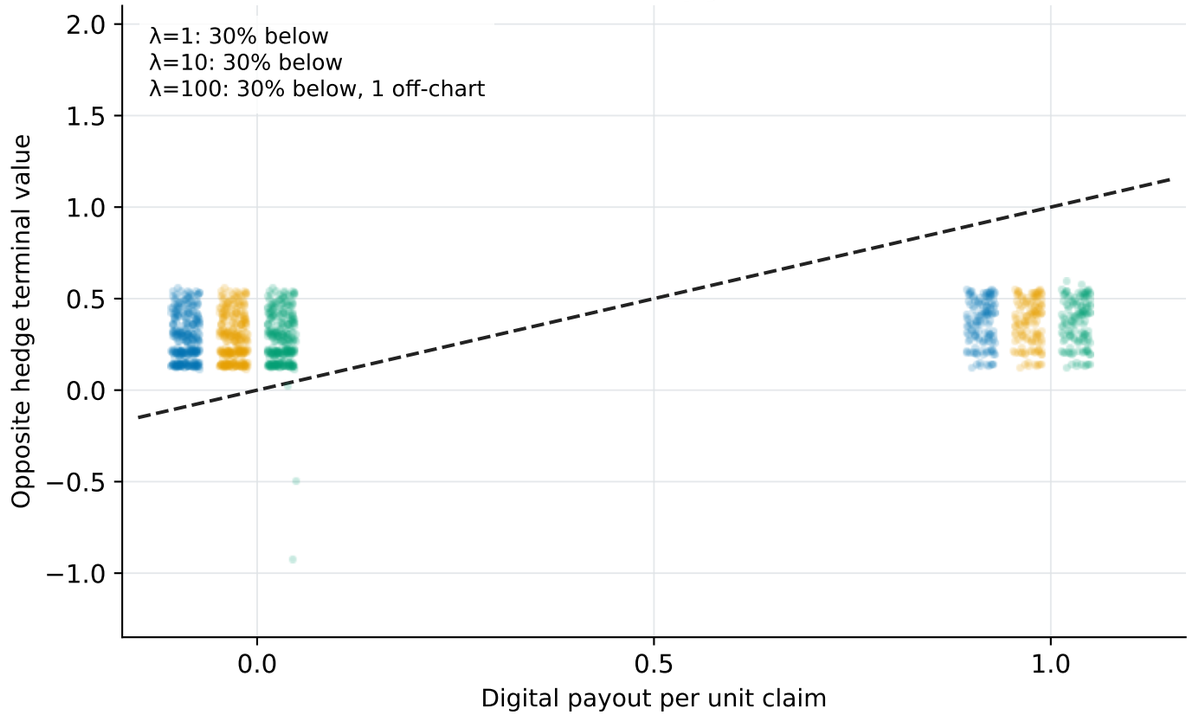

Out-of-sample market transitions; 44 dates × 10 digitals per complete cell. Below diagonal violates short-side coverage at the market premium. These are reversed long-side actions, not separately optimized superhedges.

VolGAN: opposite long-claim hedge versus digital payout

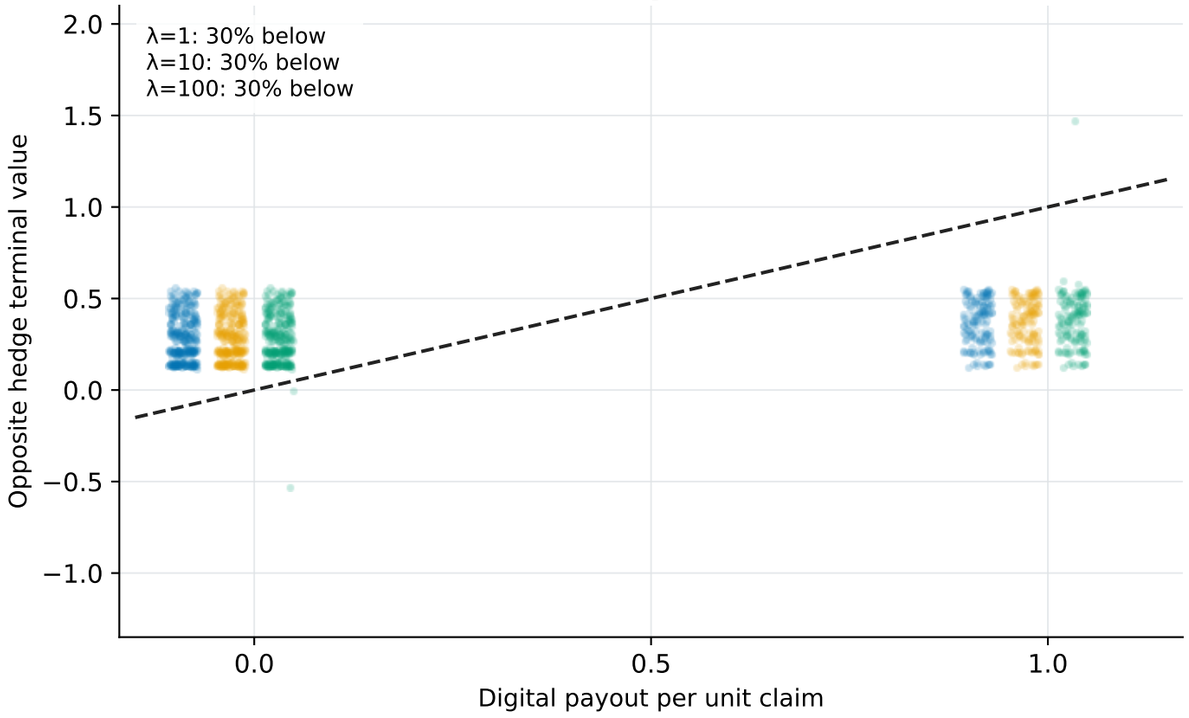

Mean-variance

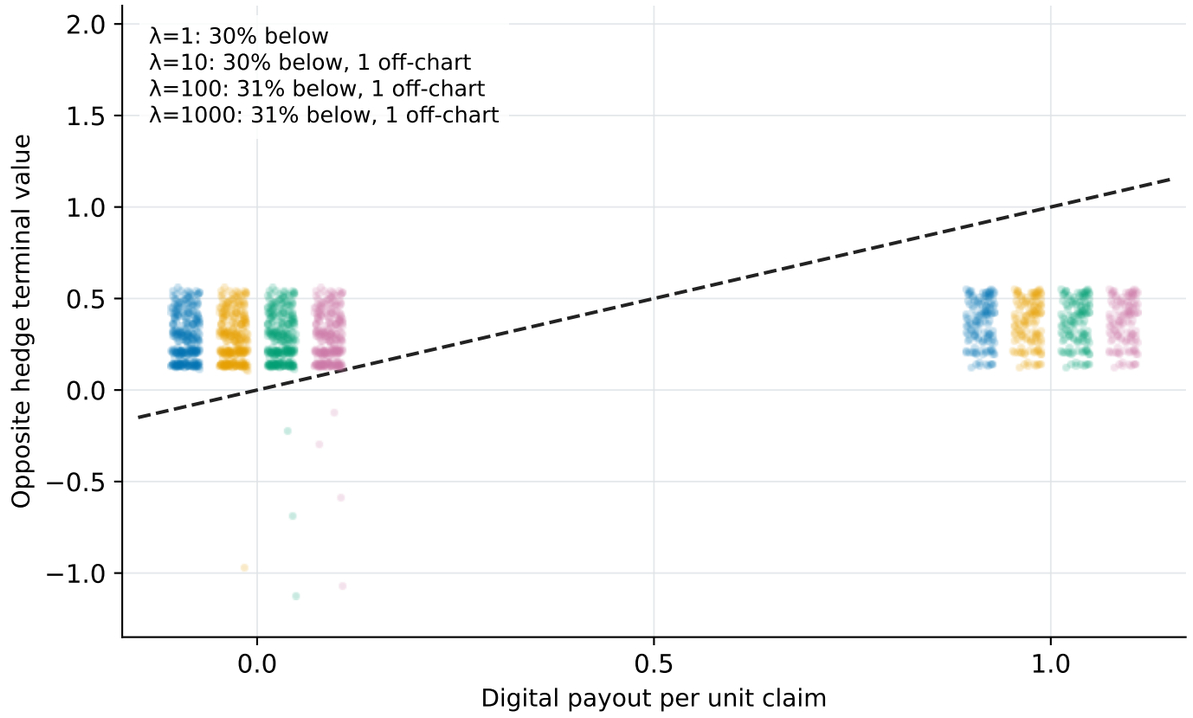

Entropy

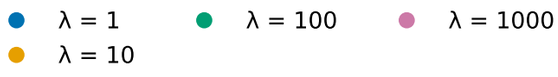

Power-exponential

CVaR OCE

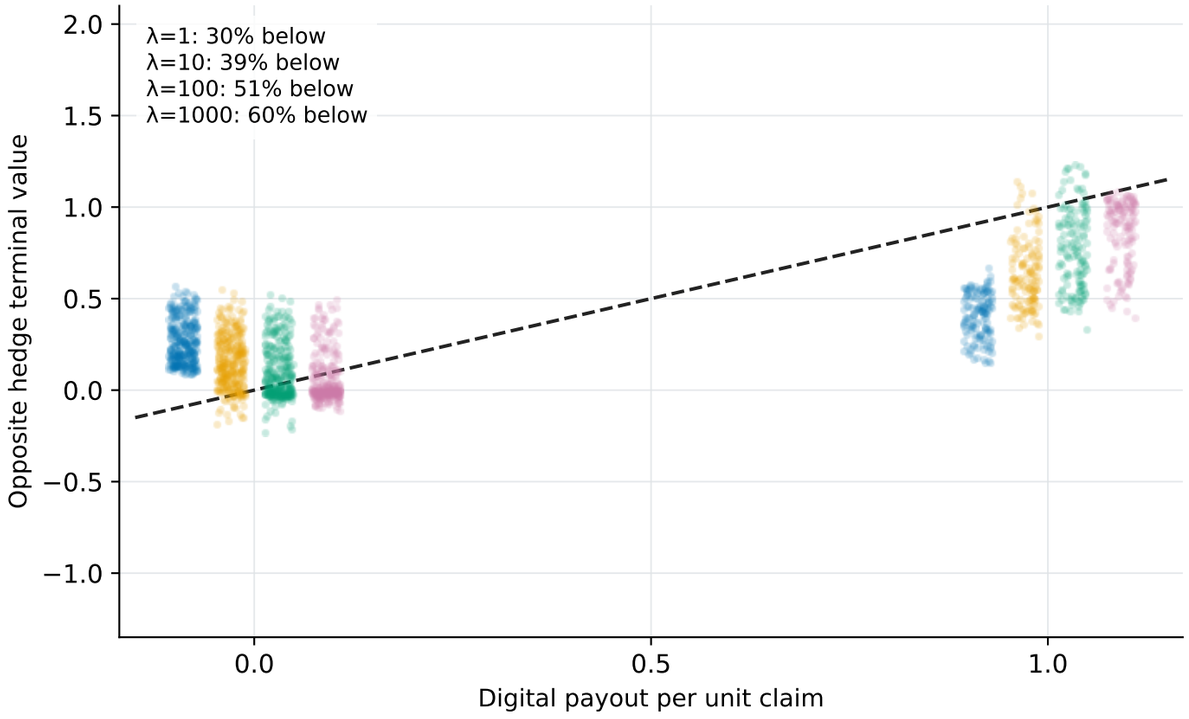

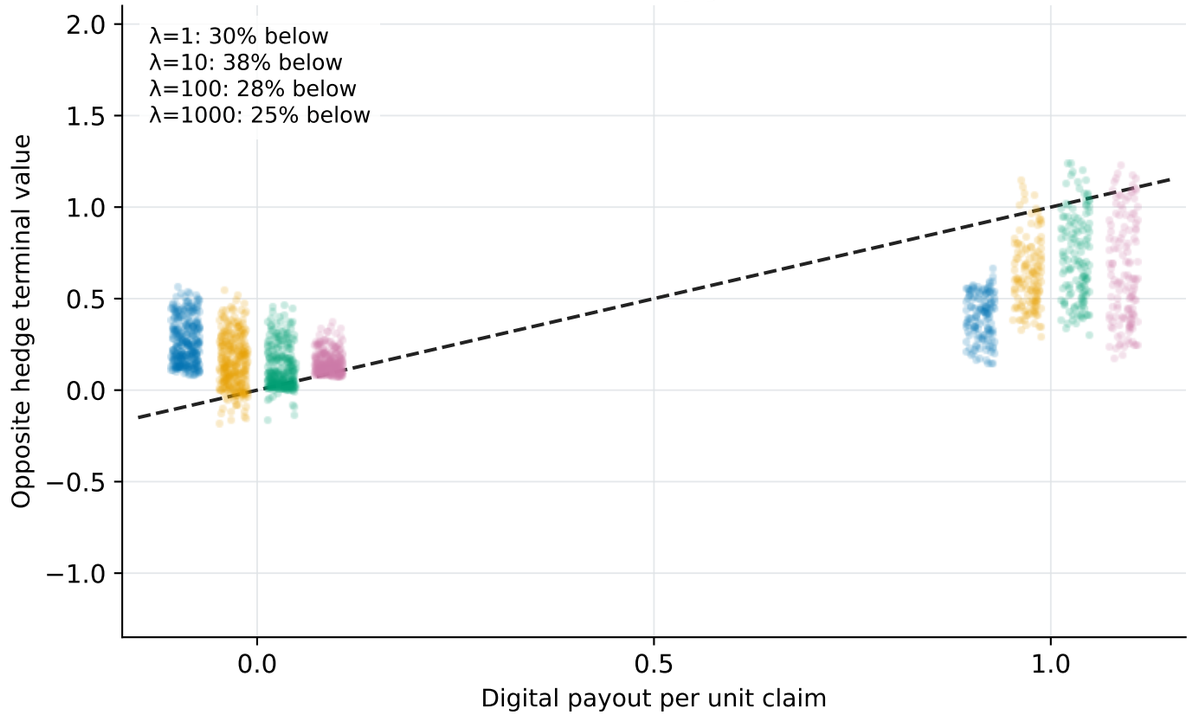

Out-of-sample market transitions; 44 dates × 10 digitals per complete cell. Below diagonal violates short-side coverage at the market premium. These are reversed long-side actions, not separately optimized superhedges.

GROMM P: opposite long-claim hedge versus digital payout

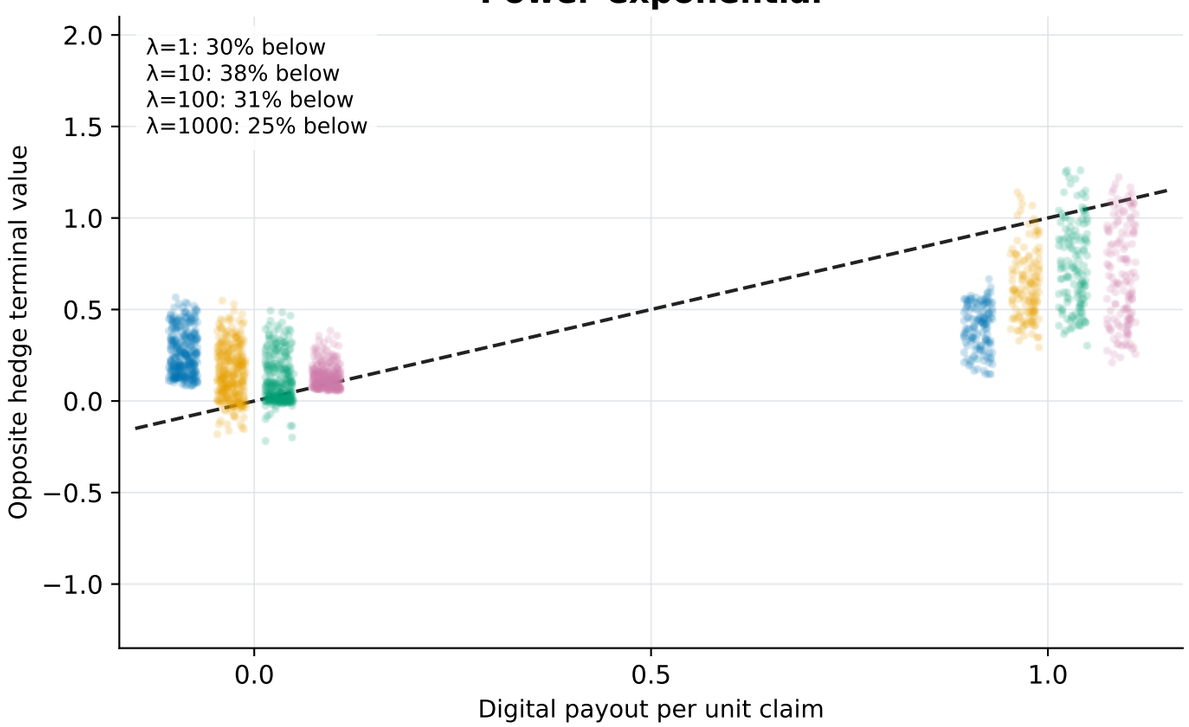

Mean-variance

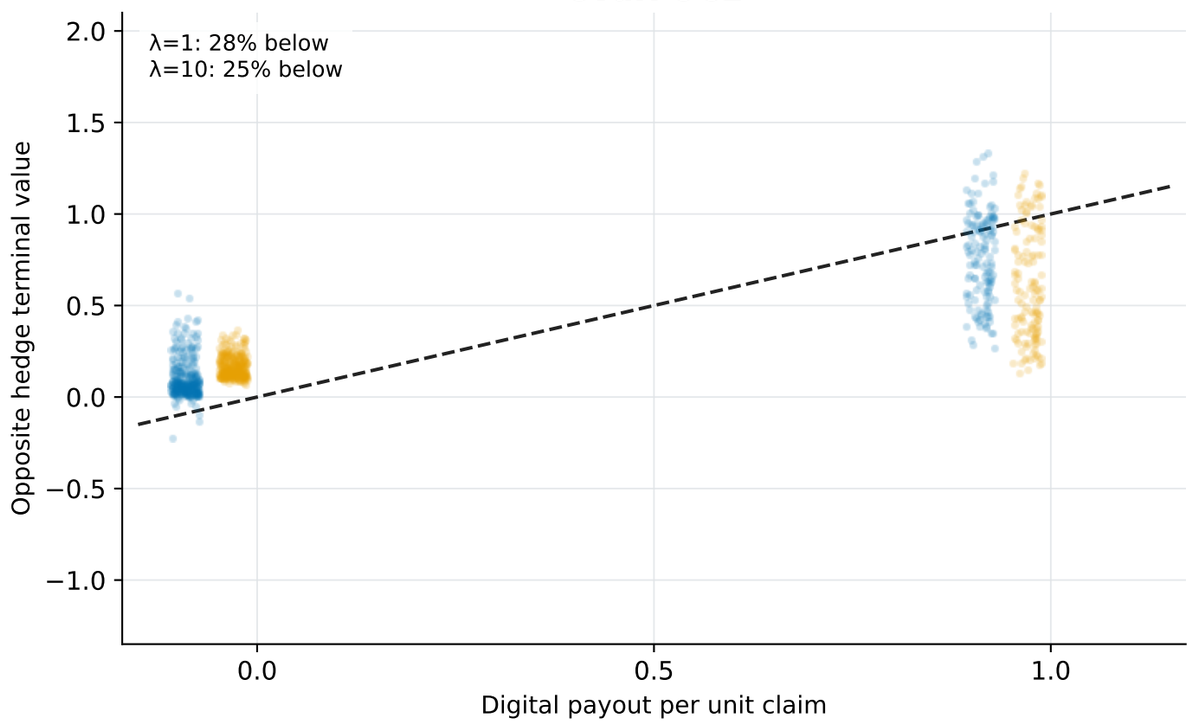

Entropy

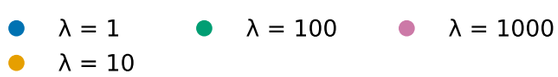

Power-exponential

CVaR OCE

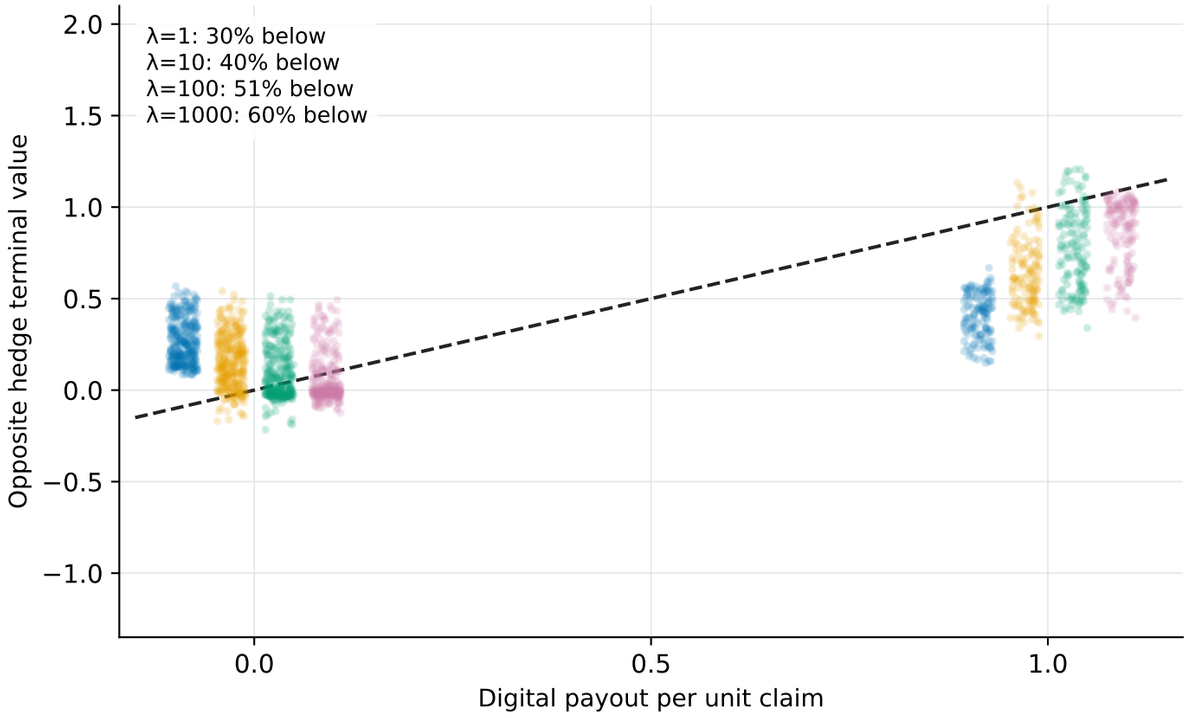

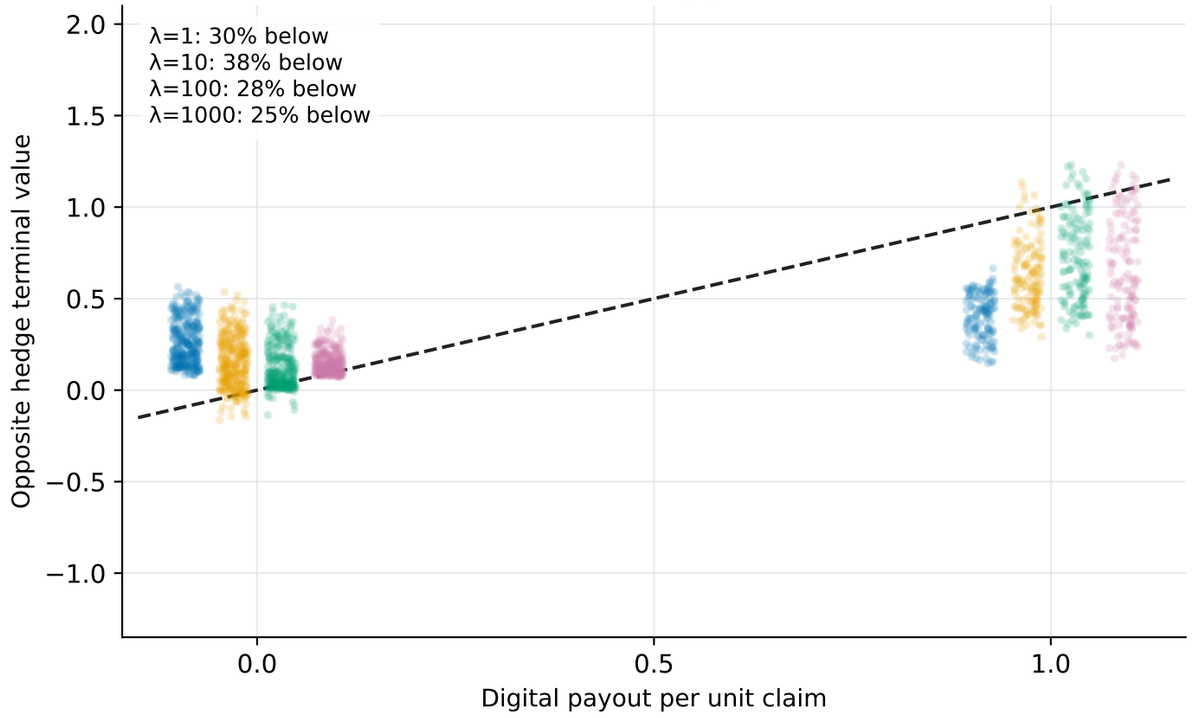

Out-of-sample market transitions; 44 dates × 10 digitals per complete cell. Below diagonal violates short-side coverage at the market premium. These are reversed long-side actions, not separately optimized superhedges.

GROMM Q: opposite long-claim hedge versus digital payout

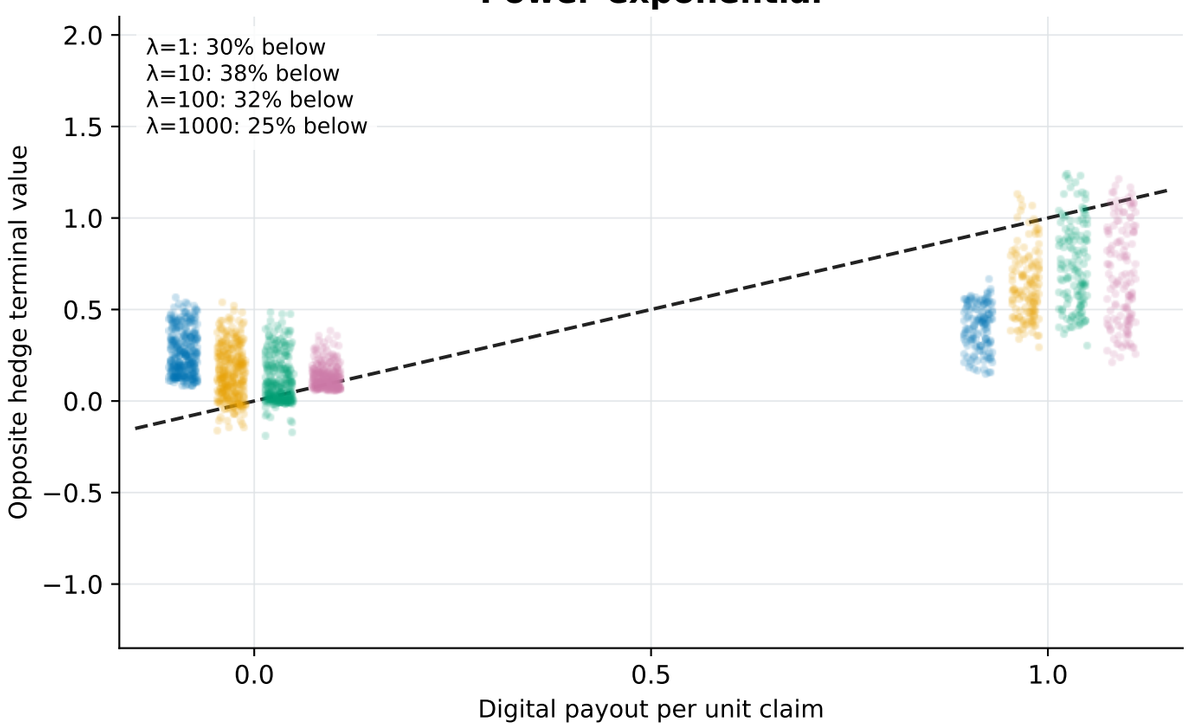

Mean-variance

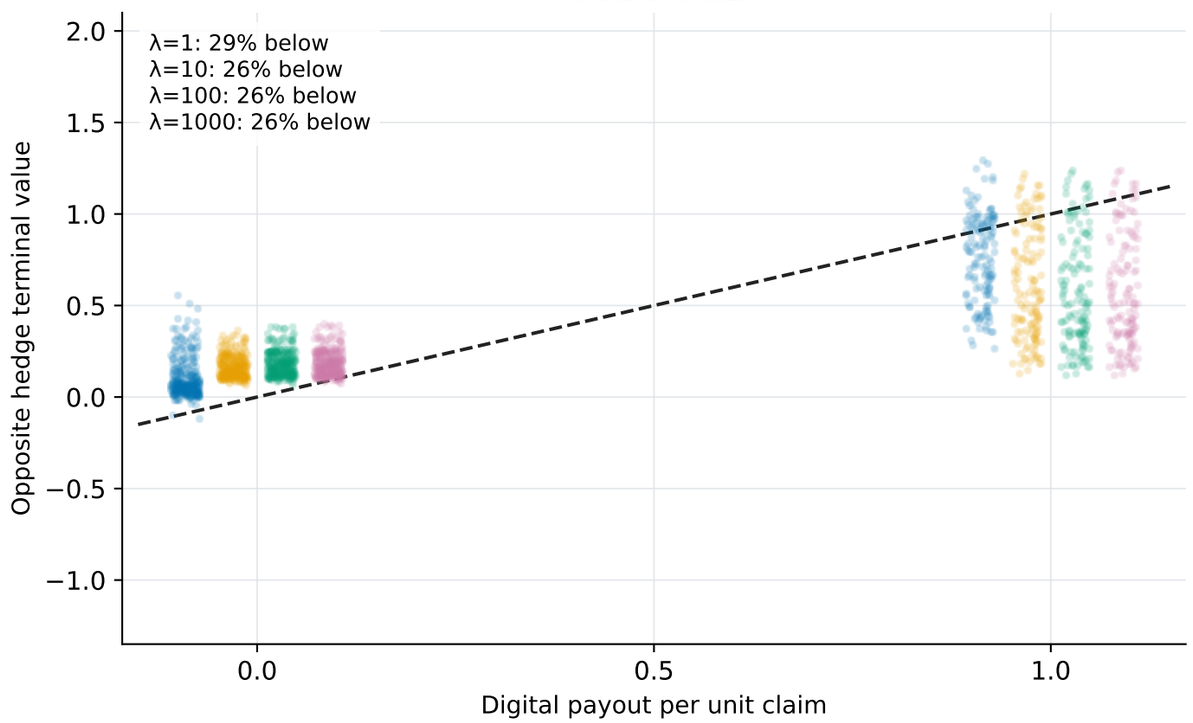

Entropy

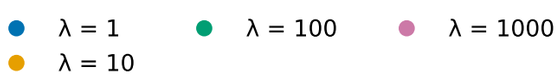

Power-exponential

CVaR OCE

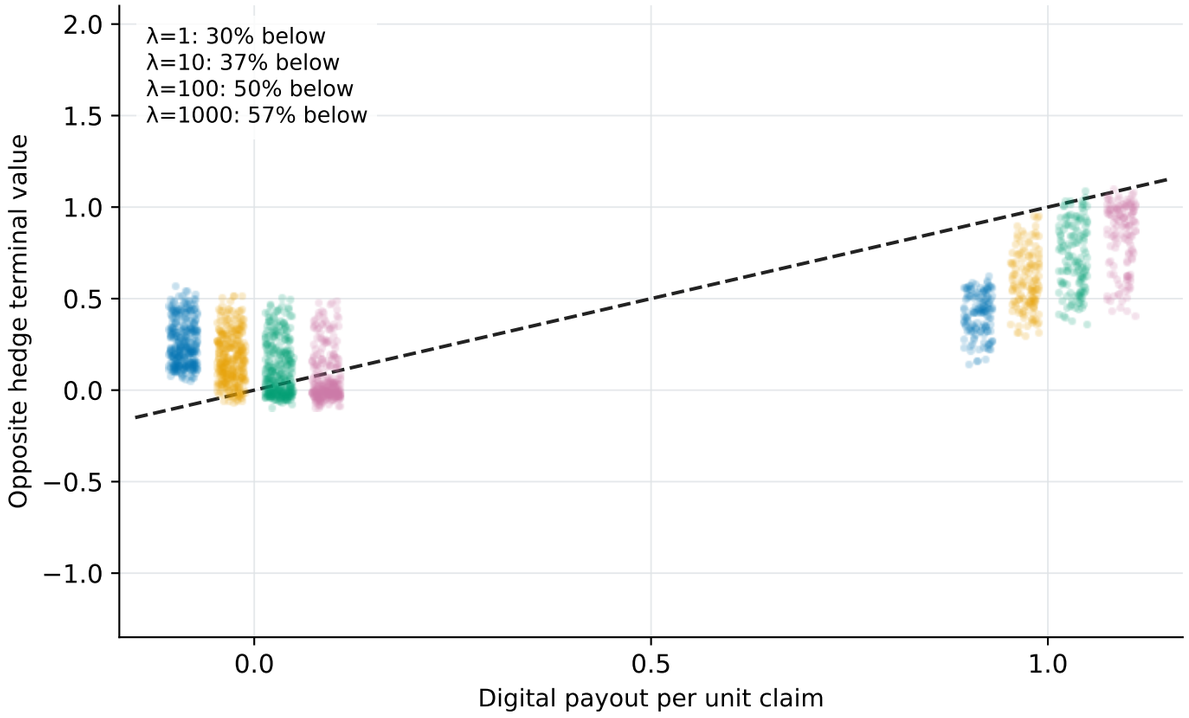

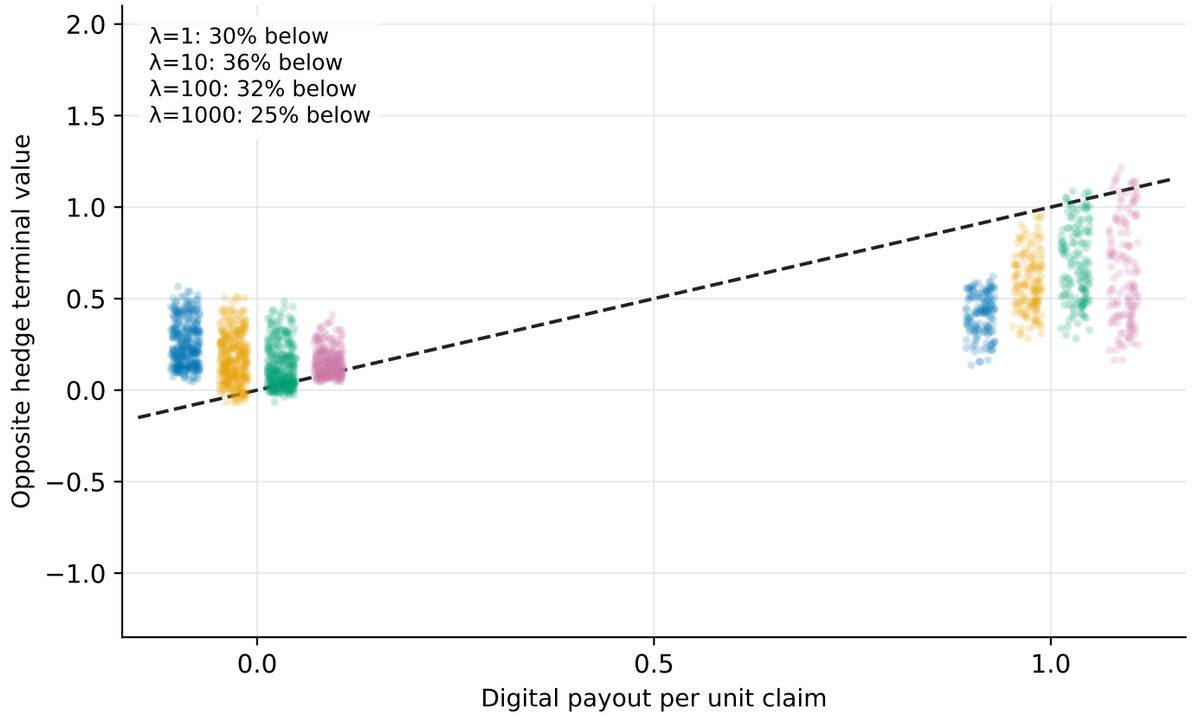

Out-of-sample market transitions; 44 dates × 10 digitals per complete cell. Below diagonal violates short-side coverage at the market premium. These are reversed long-side actions, not separately optimized superhedges.

AD-Seq-Vol: opposite long-claim hedge versus digital payout

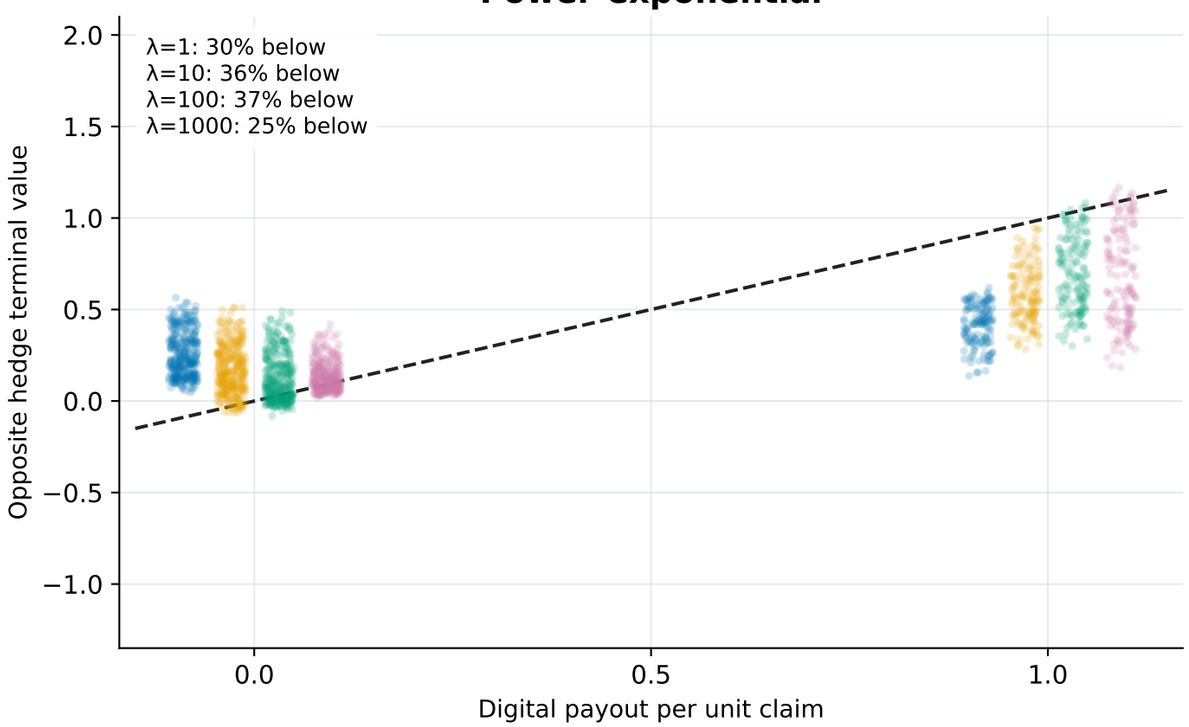

Mean-variance

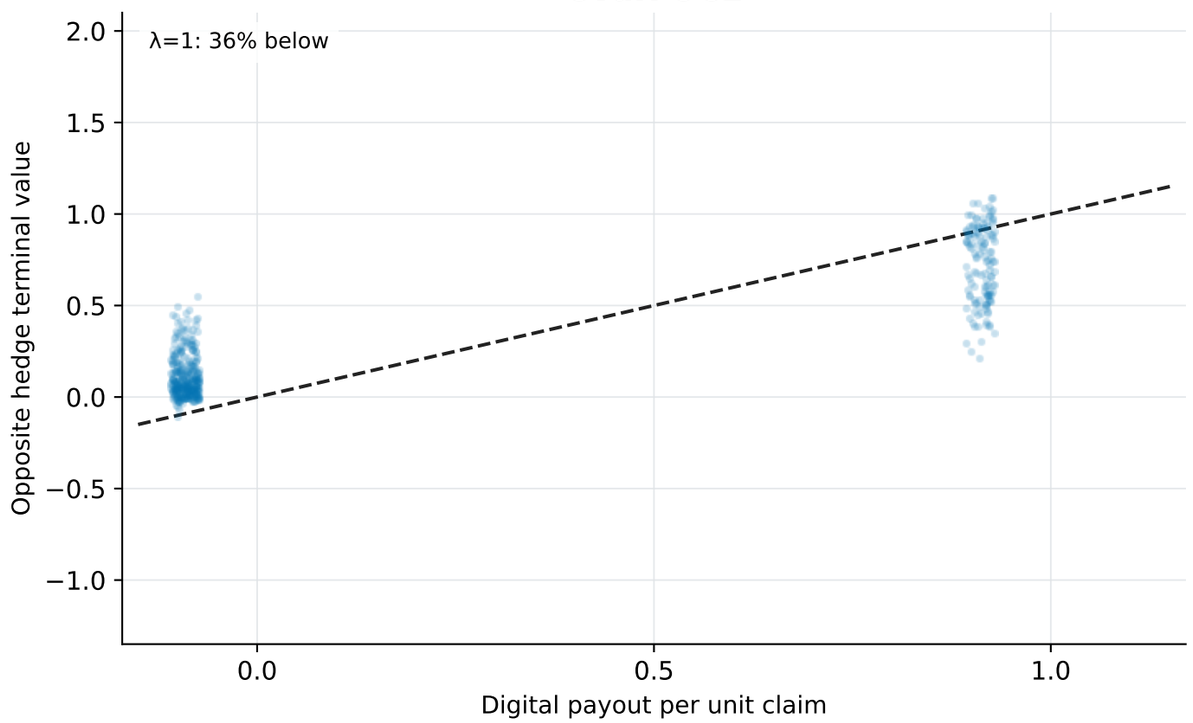

Entropy

Power-exponential

CVaR OCE

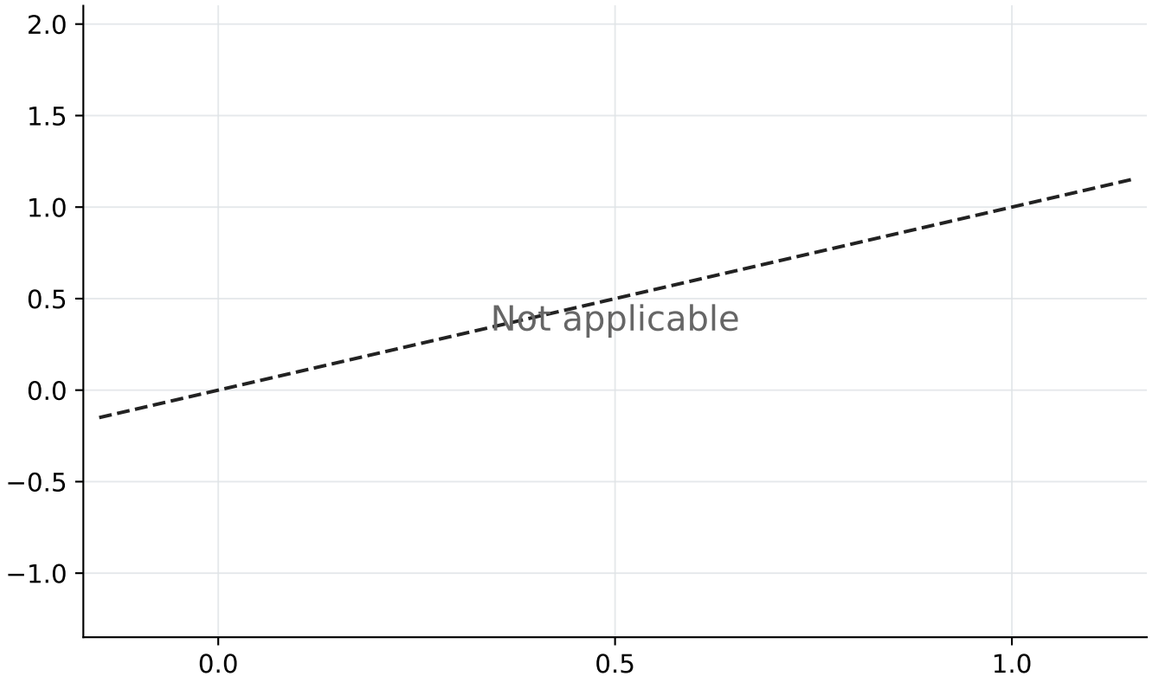

λ = 1 λ = 10 λ = 100 λ = 1000

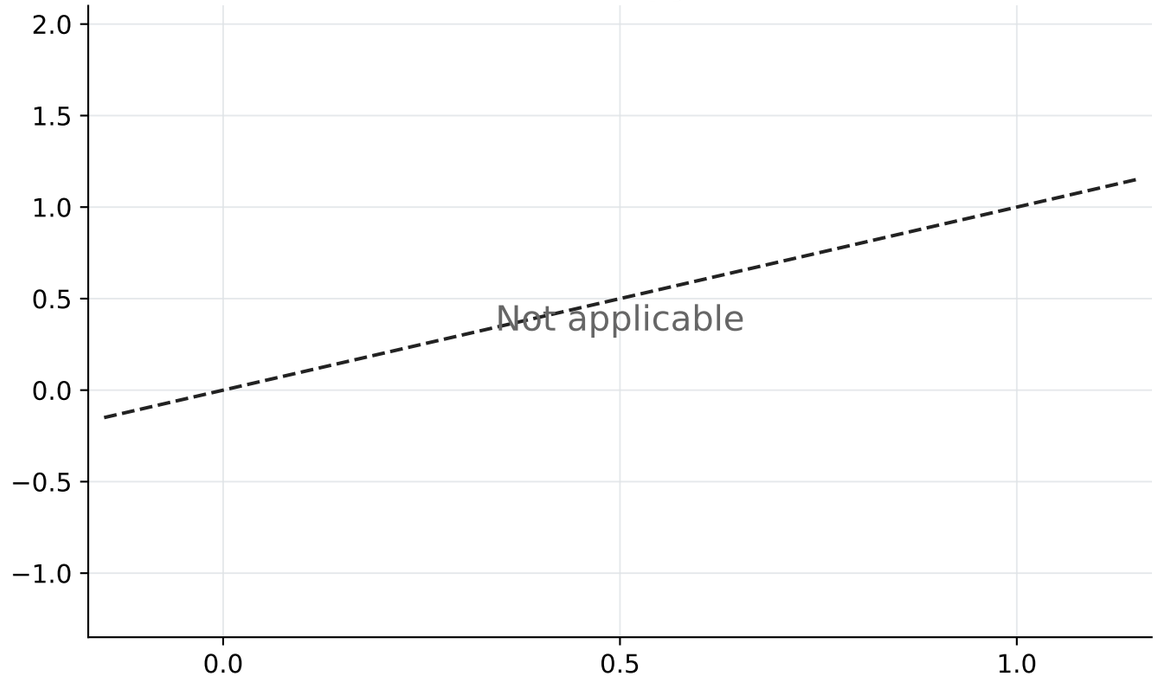

Out-of-sample market transitions; 44 dates × 10 digitals per complete cell. Below diagonal violates short-side coverage at the market premium. These are reversed long-side actions, not separately optimized superhedges.

AD-Seq-Vol-FT: opposite long-claim hedge versus digital payout

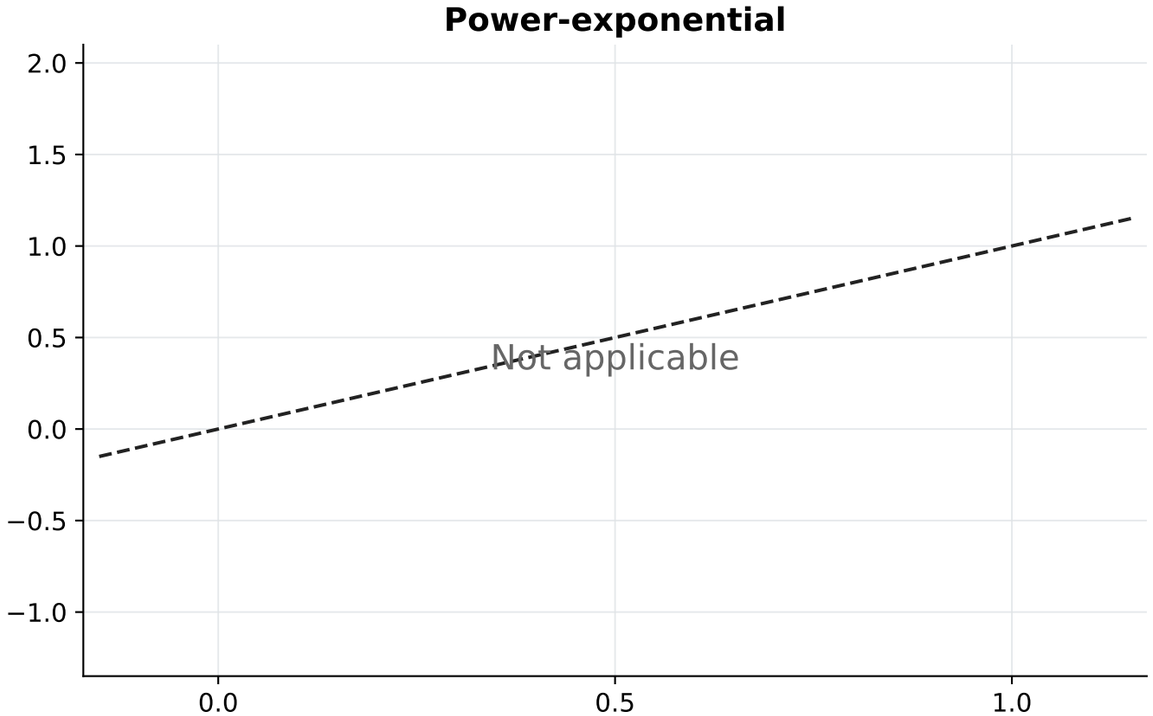

Mean–variance

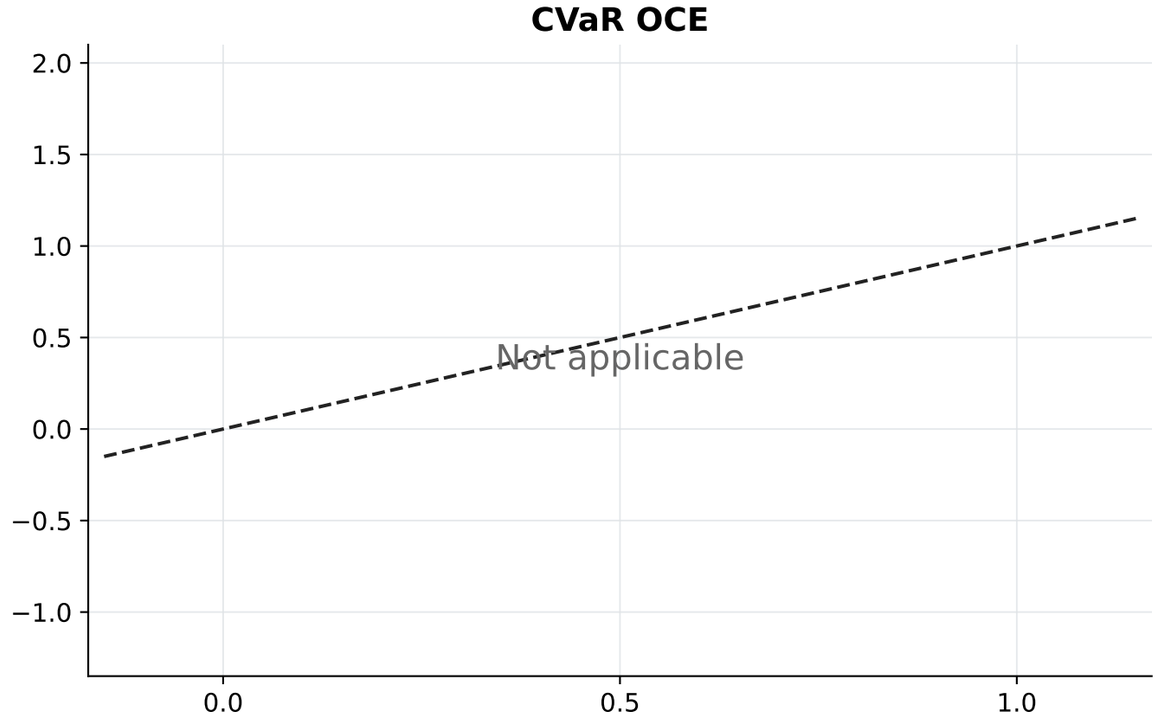

Entropy

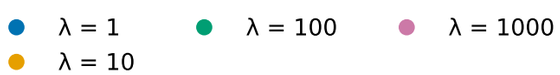

Power-exponential

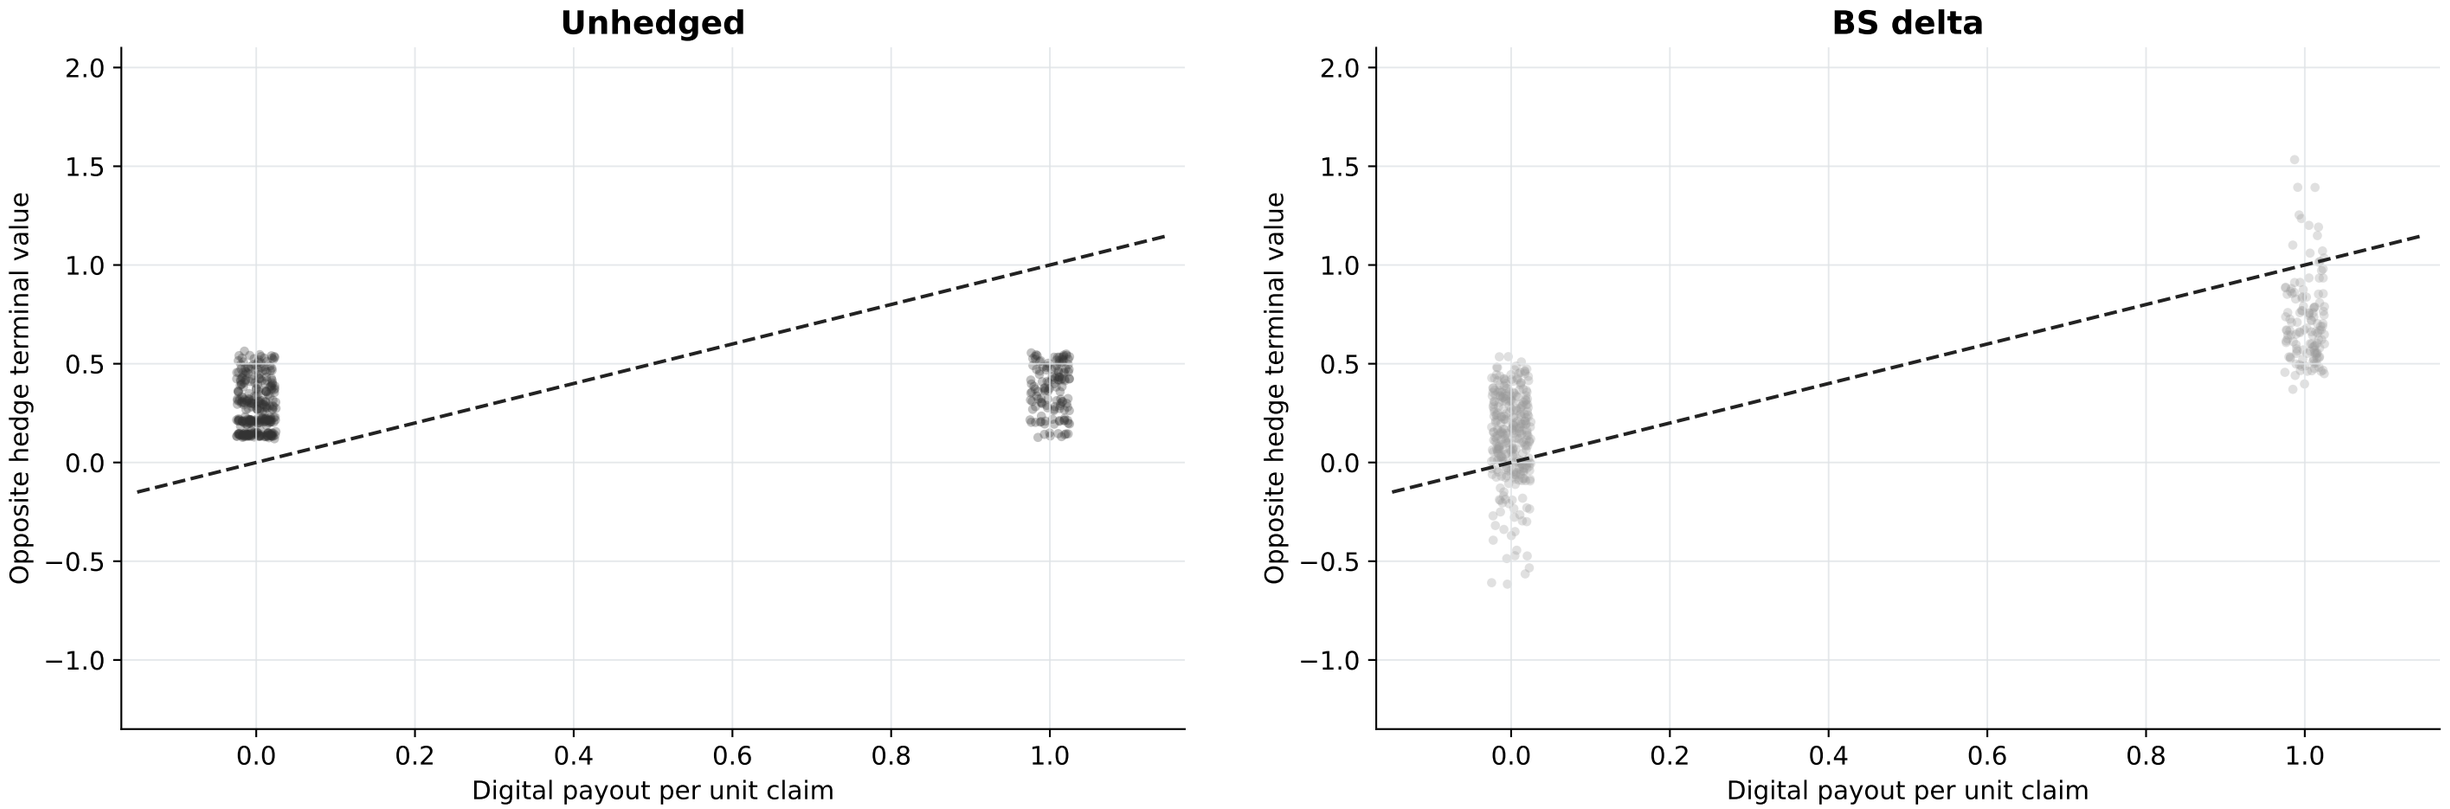

CVaR OCE

Out-of-sample market transitions; 44 dates × 10 digitals per complete cell. Below diagonal violates short-side coverage at the market premium. These are reversed long-side actions, not separately optimized superhedges.

Fixed baselines: opposite hedge versus digital payout

Below the dashed diagonal: the opposite hedge does not cover the digital payout. No short-side superhedge was optimized.
